## **Decision Tree Learning**

[read Chapter 3] [recommended exercises 3.1, 3.4]

- Decision tree representation
- ID3 learning algorithm
- Entropy, Information gain
- Overfitting

## **Decision Tree for** PlayTennis

 $\langle Outlook = Sunny, Temperature = Hot, Humidity = High, Wind = Strong \rangle$ 

#### A Tree to Predict C-Section Risk

Learned from medical records of 1000 women Negative examples are C-sections

```
[833+,167-] .83+ .17-
Fetal_Presentation = 1: [822+,116-] .88+ .12-
| Previous_Csection = 0: [767+,81-] .90+ .10-
| Primiparous = 0: [399+,13-] .97+ .03-
| Primiparous = 1: [368+,68-] .84+ .16-
| | Fetal_Distress = 0: [334+,47-] .88+ .12-
| | Birth_Weight < 3349: [201+,10.6-] .95+ .05-
| | Birth_Weight >= 3349: [133+,36.4-] .78+ .2-
| Previous_Csection = 1: [55+,35-] .61+ .39-
Fetal_Presentation = 2: [3+,29-] .11+ .89-
Fetal_Presentation = 3: [8+,22-] .27+ .73-
```

#### **Decision Trees**

#### Decision tree representation:

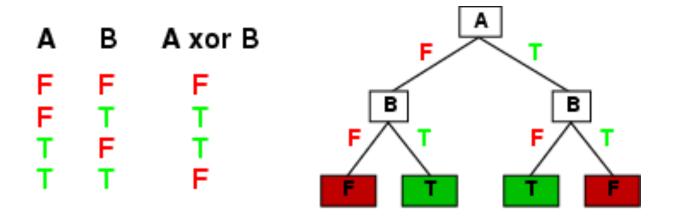

- Each internal node tests an attribute
- Each branch corresponds to attribute value
- Each leaf node assigns a classification

#### How would we represent:

- $\bullet \land, \lor, XOR$
- $\bullet \ (A \land B) \lor (C \land \neg D \land E)$
- $\bullet M \text{ of } N$

# **Expressiveness of Decision Trees**

 Can express any function of input attributes, e.g., for Boolean functions, truth table row → path to leaf:

- There's a consistent decision tree for any training set with one path to leaf for each example, but it probably won't generalize to new examples
- Prefer more compact decision trees

#### When to Consider Decision Trees

- Instances describable by attribute–value pairs
- Target function is discrete valued
- Disjunctive hypothesis may be required
- Possibly noisy training data

#### Examples:

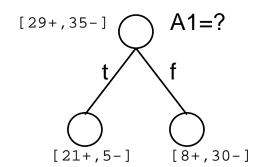

- Equipment or medical diagnosis
- Credit risk analysis
- Modeling calendar scheduling preferences

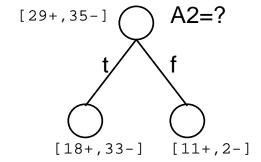

## Top-Down Induction of Decision Trees

#### Main loop:

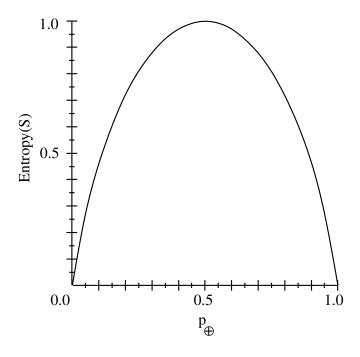

- 1.  $A \leftarrow$  the "best" decision attribute for next node
- 2. Assign A as decision attribute for node
- 3. For each value of A, create new descendant of node
- 4. Sort training examples to leaf nodes
- 5. If training examples perfectly classified, Then STOP, Else iterate over new leaf nodes

#### Which attribute is best?

## Entropy

- $\bullet$  S is a sample of training examples
- $p_{\oplus}$  is the proportion of positive examples in S
- ullet  $p_{\ominus}$  is the proportion of negative examples in S
- ullet Entropy measures the impurity of S

$$Entropy(S) \equiv -p_{\oplus} \log_2 p_{\oplus} - p_{\ominus} \log_2 p_{\ominus}$$

## Entropy

Entropy(S) =expected number of bits needed to encode class  $(\oplus \text{ or } \ominus)$  of randomly drawn member of S (under the optimal, shortest-length code)

#### Why?

Information theory: optimal length code assigns  $-\log_2 p$  bits to message having probability p.

So, expected number of bits to encode  $\oplus$  or  $\ominus$  of random member of S:

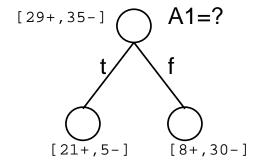

$$p_{\oplus}(-\log_2 p_{\oplus}) + p_{\ominus}(-\log_2 p_{\ominus})$$

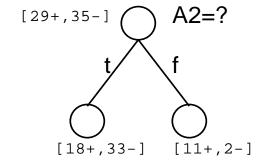

$$Entropy(S) \equiv -p_{\oplus} \log_2 p_{\oplus} - p_{\ominus} \log_2 p_{\ominus}$$

### **Information Gain**

Gain(S, A) =expected reduction in entropy due to sorting on A

$$Gain(S, A) \equiv Entropy(S) - \sum_{v \in Values(A)} \frac{|S_v|}{|S|} Entropy(S_v)$$

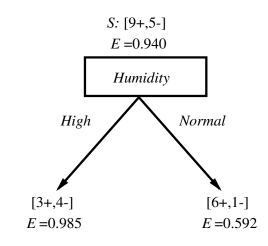

## Training Examples

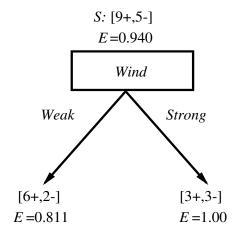

Day	Outlook	Temperature	Humidity	Wind	PlayTennis
D1	Sunny	Hot	High	Weak	No
D2	Sunny	$\operatorname{Hot}$	$\operatorname{High}$	Strong	No
D3	Overcast	$\operatorname{Hot}$	$\operatorname{High}$	Weak	Yes
D4	Rain	Mild	$\operatorname{High}$	Weak	Yes
D5	Rain	Cool	Normal	Weak	Yes
D6	Rain	Cool	Normal	Strong	No
D7	Overcast	Cool	Normal	Strong	Yes
D8	Sunny	Mild	$\operatorname{High}$	Weak	No
D9	Sunny	Cool	Normal	Weak	Yes
D10	Rain	Mild	Normal	Weak	Yes
D11	Sunny	Mild	Normal	Strong	Yes
D12	Overcast	Mild	$\operatorname{High}$	Strong	Yes
D13	Overcast	$\operatorname{Hot}$	Normal	Weak	Yes
D14	Rain	Mild	$\operatorname{High}$	Strong	No

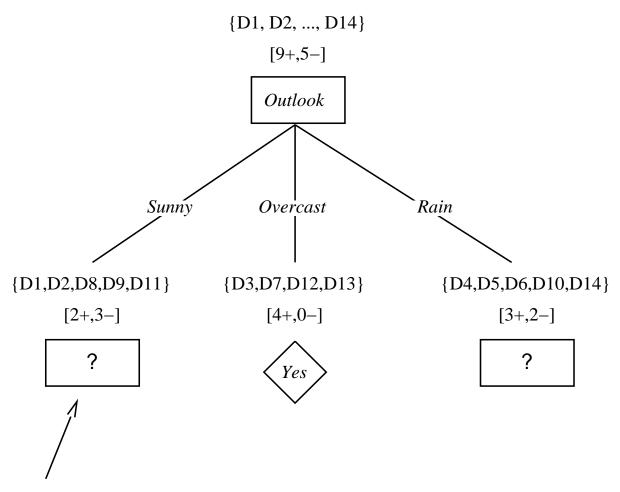

## Selecting the Next Attribute

#### Which attribute is the best classifier?

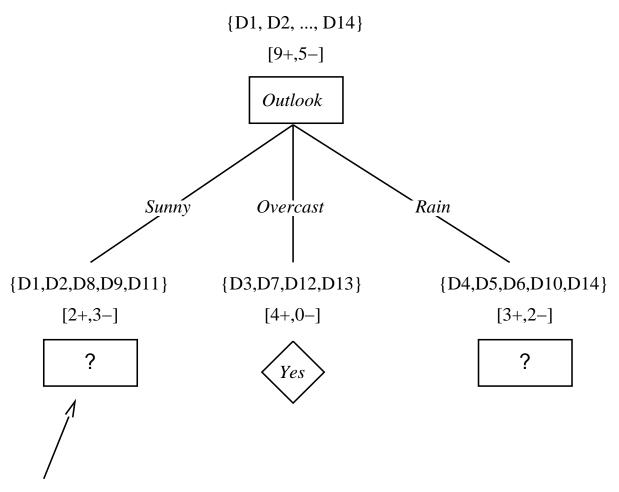

Which attribute should be tested here?

Which attribute should be tested here?

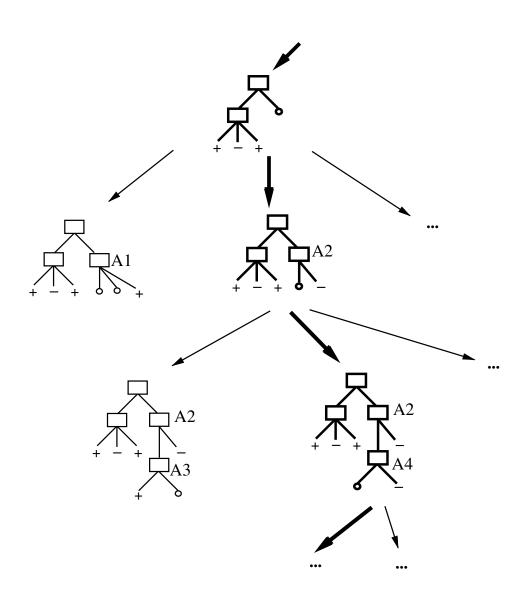

$$S_{sunny} = \{D1,D2,D8,D9,D11\}$$

$$Gain (S_{sunny}, Humidity) = .970 - (3/5) 0.0 - (2/5) 0.0 = .970$$

$$Gain (S_{sunny}, Temperature) = .970 - (2/5) 0.0 - (2/5) 1.0 - (1/5) 0.0 = .570$$

$$Gain (S_{sunny}, Wind) = .970 - (2/5) 1.0 - (3/5) .918 = .019$$

## Hypothesis Space Search by ID3

## Hypothesis Space Search by ID3

- Hypothesis space is complete!
  - Target function surely in there...
- Outputs a single hypothesis (which one?)
  - Can't play 20 questions...
- No back tracking
  - Local minima...
- Statistically-based search choices
  - Robust to noisy data...
- Inductive bias: approx "prefer shortest tree"

#### Inductive Bias in ID3

Note H is the power set of instances X

 $\rightarrow$ Unbiased?

Not really...

- Preference for short trees, and for those with high information gain attributes near the root
- Bias is a preference for some hypotheses, rather than a restriction of hypothesis space H
- Occam's razor: prefer the shortest hypothesis that fits the data

#### Occam's Razor

Why prefer short hypotheses?

#### Argument in favor:

- Fewer short hyps. than long hyps.
- → a short hyp that fits data unlikely to be coincidence
- $\rightarrow$  a long hyp that fits data might be coincidence

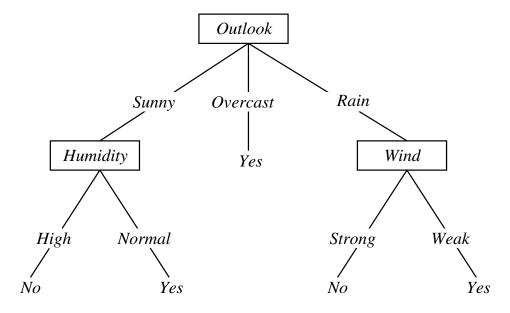

#### Argument opposed:

- There are many ways to define small sets of hyps
- e.g., all trees with a prime number of nodes that use attributes beginning with "Z"
- What's so special about small sets based on *size* of hypothesis??

## Overfitting in Decision Trees

Consider adding noisy training example #15:

Sunny, Hot, Normal, Strong, PlayTennis = No What effect on earlier tree?

### Overfitting

Consider error of hypothesis h over

- training data:  $error_{train}(h)$
- entire distribution  $\mathcal{D}$  of data:  $error_{\mathcal{D}}(h)$

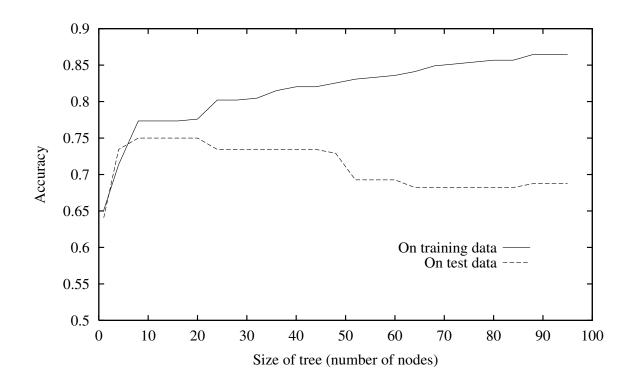

Hypothesis  $h \in H$  overfits training data if there is an alternative hypothesis  $h' \in H$  such that

$$error_{train}(h) < error_{train}(h')$$

and

$$error_{\mathcal{D}}(h) > error_{\mathcal{D}}(h')$$

## Overfitting in Decision Tree Learning

## Avoiding Overfitting

#### How can we avoid overfitting?

- stop growing when data split not statistically significant
- grow full tree, then post-prune

#### How to select "best" tree:

- Measure performance over training data
- Measure performance over separate validation data set
- MDL: minimize size(tree) + size(misclassifications(tree))

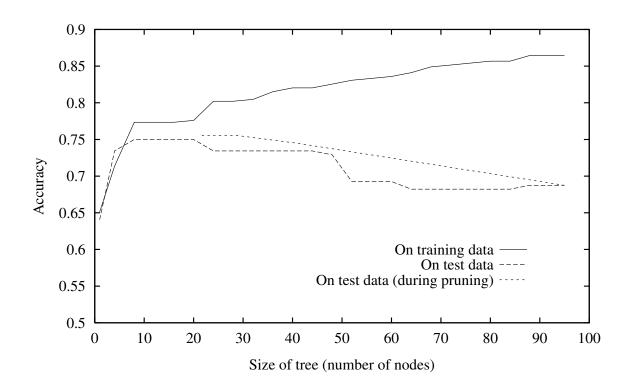

## Reduced-Error Pruning

Split data into training and validation set

Do until further pruning is harmful:

- 1. Evaluate impact on *validation* set of pruning each possible node (plus those below it)
- 2. Greedily remove the one that most improves validation set accuracy
- produces smallest version of most accurate subtree
- What if data is limited?

## Effect of Reduced-Error Pruning

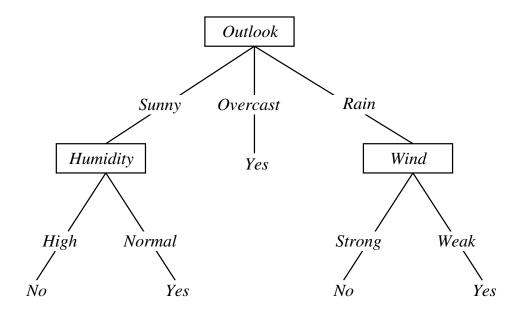

## Rule Post-Pruning

- 1. Convert tree to equivalent set of rules
- 2. Prune each rule independently of others
- 3. Sort final rules into desired sequence for use

Perhaps most frequently used method (e.g., C4.5)

## Converting A Tree to Rules

$$\begin{array}{ll} \text{IF} & (Outlook = Sunny) \land (Humidity = High) \\ \text{THEN} & PlayTennis = No \end{array}$$

$$\begin{array}{ll} \text{IF} & (Outlook = Sunny) \land (Humidity = Normal) \\ \text{THEN} & PlayTennis = Yes \end{array}$$

. . .

### Continuous Valued Attributes

Create a discrete attribute to test continuous

- Temperature = 82.5
- (Temperature > 72.3) = t, f

Temperature:404860728090PlayTennis:NoNoYesYesYesNo

### Attributes with Many Values

#### Problem:

- If attribute has many values, Gain will select it
- Imagine using  $Date = Jun_3_1996$  as attribute

One approach: use GainRatio instead

$$GainRatio(S,A) \equiv \frac{Gain(S,A)}{SplitInformation(S,A)}$$

$$SplitInformation(S, A) \equiv -\sum_{i=1}^{c} \frac{|S_i|}{|S|} \log_2 \frac{|S_i|}{|S|}$$

where  $S_i$  is subset of S for which A has value  $v_i$ 

#### Attributes with Costs

#### Consider

- $\bullet$  medical diagnosis, BloodTest has cost \$150
- robotics,  $Width\_from\_1ft$  has cost 23 sec.

How to learn a consistent tree with low expected cost?

One approach: replace gain by

• Tan and Schlimmer (1990)

$$rac{Gain^2(S,A)}{Cost(A)}.$$

• Nunez (1988)

$$\frac{2^{Gain(S,A)}-1}{(Cost(A)+1)^w}$$

where  $w \in [0, 1]$  determines importance of cost

#### Unknown Attribute Values

What if some examples missing values of A? Use training example anyway, sort through tree

- If node n tests A, assign most common value of A among other examples sorted to node n
- assign most common value of A among other examples with same target value
- assign probability  $p_i$  to each possible value  $v_i$  of A
  - assign fraction  $p_i$  of example to each descendant in tree

Classify new examples in same fashion
